## Conservation Genetics Practice Problems #3

1) What is the standard deviation of a continuously distributed phenotype with variance of $V_P$=42?

2) Describe what the variables $+a$, $-a$, and $d$ tell us about inheritence and trait values.

3) What can you infer if $d$ is closer to $-a$ than $a$?

4) What is the heritability of a trait that has a covariance in parent-offspring values of $COV_{PO}=$15 and overall variance of $V_P$=60?

5) Generally speaking, does a single locus have a bigger impact on phenotypes in traditional Mendelian genetics or quantitative genetics?
